TITLE: Description of inelastic diffraction scattering by the complex angular momentum method 21, 44, 55

SOURCE: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 49, no. 6, 1965, 1824-1830

TOPIC TAGS: particle diffraction, inelastic scattering, scattering cross section, alpha particle reactions

ABSTRACT: A new method, which has recently been proposed by one of the authors (Inopin, ZhETF v. 48, 1620, 1965) for the description of elastic diffraction scattering by composite nuclei, and which is shown in a companion paper (Inopin, with A. A. Kresnin ZhETF v. 49, 1796, 1965, ACC NR: AP6002720) to be in agreement with the available experimental data, is used to obtain a unified description of elastic

L 17654-66

ACC NR: AP6002723

and inelastic scattering of spinless particles. A simple analytic expression for the inelastic scattering cross section is derived on the basis of the complex angular momentum method. The S-matrix parameters introduced in the earlier papers are used for the inelastic scattering in this paper. The expression obtained yields the well known Blair phase rule, for which a more rigorous proof is obtained in this paper than in the past. The results are compared with experiments on the scattering of α particles by five different nuclei (Mg^{24} , Ti^{48} , Ni^{58} , Zn^{66} , Sr^{88}), and the comparison indicates satisfactory qualitative agreement between the theory and the experimental data. The authors thank N. Austern and J. S. Blair for sending a preprint of their paper before publication, and to A. A. Kresnin for valuable discussions. TITLE: Contribution to the theory of diffraction scattering of particles by nuclei¹⁹
based on the method of complex angular moments

SOURCE: Zh eksper i teor fiz, v. 50, no. 6, 1966, 1674-1681

TOPIC TAGS: particle diffraction, Coulomb scattering, S matrix, elastic scattering,
scattering cross section

ABSTRACT: Expressions for elastic and inelastic diffraction scattering of particles
by nuclei, involving the excitation of collective states, have been obtained by the
method of complex angular moments. It has been assumed that the modulus and the
phase shift of the S matrix may possess poles in the complex angular momentum
plane. It has been shown that the presence of poles in the S matrix phase near the

Card 1/2

L 4309 -66

ACC NR: AP6020225

poles of its modulus and the Coulomb interaction explains a number of interesting features of the behavior of the differential scattering cross sections, such as the decrease of oscillation amplitudes of the cross sections with growth of the nuclear charge, the possibility of inelastic scattering cross-section oscillations when oscillations are absent in elastic scattering, and the decrease of oscillation amplitude with the growth of the scattering angle. It has been shown that "competition" between the Coulomb and nuclear phases can explain the "cross-section drop" (the presence of one or two cross-section minima which are much lower than the adjoining ones). It has been mentioned that the value $\delta(\theta_0)$, where θ_0 is the boundary nuclear angular momentum, can readily be estimated. The authors thank Ye. V. Inopin for his interest in this work and for a number of valuable discussions. Orig. art. has: 33 formulas. [Based on authors' abstract] [NT]

TOPIC TAGS: combustion analysis, burning rate measurement, coal

ABSTRACT: The author points out that incomplete combustion of pulverized lean coal and anthracite in electric-station boilers can reach 40%, that there are no reliable theoretical means of calculating the degree of combustion, and that the usual station tests fail to take account of numerous factors. He consequently proposes an new method for calculating the degree of combustion, based on a new theory of combustion of pulverized coal. The author also discusses the position of the theory itself as a method for calculating the degree of combustion. Theoretical data on the degree of combustion of pulverized coal are presented.

Card 1

the coefficient of incomplete combustion was checked experimentally for pulverized-coal burners of the boilers in various electric stations, and referenced to the published test reports. The experimental results agree with those given by the formula within ± 0.04 . The formula is valid for the range of parameters:

AUTHORS: Kresnin, A.A. and Tishchenko, B.Y.

TITLE: Polarization effects in the scattering of electrons by nuclei

PERIODICAL: Ukrayins'kyy fizychnyy zhurnal, v. 5, no. 4, 1960, 437-443

TEXT: The scattering cross-section, the azimuthal asymmetry and the polarization of the scattered electrons are calculated. Electron scattering by nuclei with Yukawa charge-density distribution is considered in the second Born-approximation. The Yukawa charge-density distribution is

$$\rho(r) = \frac{x^2}{4\pi} \cdot \frac{e^{-xr}}{r} \quad (4)$$

For describing the polarization of the scattered electrons, the method of density matrices is used. For the cross-section one ob-

Card 1/6

D274/D306

tains

$$\frac{d\sigma}{d\Omega} = \left(\frac{Ze^2}{2mv^2 \sin^2 x} \right)^2 \frac{(1-v^2)(1-v^2 \sin^2 x)}{(1+\alpha^2 \sin^2 x)^2} \times$$

$$\times \left\{ 1 + Ze^2 v \frac{1+\alpha^2 \sin^2 x}{1-v^2 \sin^2 x} \sin x [\delta_1 - (1-v^2)^{\frac{1}{2}} \operatorname{tg} x (\vec{\zeta}_1 \vec{q}_1) \delta_2] \right\}, \quad (18)$$

where δ_1 and δ_2 are given by expressions involving v^2 , α and trigonometric functions of x , (x being half the scattering angle ϑ , and $\alpha = 2p/\hbar$). If $\alpha \gg 1$, the cross section is

$$\frac{d\sigma}{d\Omega} = \left(\frac{Ze^2}{2mv^2 \sin^2 x} \right)^2 \frac{(1-v^2)(1-v^2 \sin^2 x)}{(1+\alpha^2 \sin^2 x)^2} \times$$

$$\times \left\{ 1 + Ze^2 v \frac{1+\alpha^2 \sin^2 x}{1-v^2 \sin^2 x} \sin x \left[\pi \left(1 - \sin x - \frac{2\alpha^2}{v^2} \sin x (1-v^2 \sin^2 x) \right) + \right. \right.$$

$$\left. + 2(1-v^2)^{\frac{1}{2}} \frac{\sin^2 x}{\cos x} (\ln \sin x + \alpha^2 (1 - \sin x)) (\vec{\zeta}_1 \vec{n}) \right] \right\}. \quad (22)$$

Card 2/6

Polarization effects...

S/185/60/005/004/001/021
D274/D306

For $\alpha = 0$, formula (22) coincides with the well-known formula for scattering cross-section of electrons in a Coulomb field. For $\alpha \ll 1$, another expression for the cross-section is obtained. In case of positron scattering, Ze^2 has to be replaced by $(-Ze^2)$. If a polarized electron beam is scattered, azimuthal asymmetry arises, i.e. dependence of cross-section on azimuth φ . Defining the azimuthal asymmetry by

$$\gamma = \frac{\frac{d\sigma}{d\Omega}(\varphi=0) - \frac{d\sigma}{d\Omega}(\varphi=\pi)}{\frac{d\sigma}{d\Omega}(\varphi=0) + \frac{d\sigma}{d\Omega}(\varphi=\pi)}, \quad (25)$$

one obtains

$$\gamma = -Ze^2 v (1-v^2)^{1/2} \frac{1 + a^2 \sin^2 x \frac{\sin^2 x}{\cos x}}{1 - v^2 \sin^2 x} \delta_2(\vec{\zeta}, \vec{n}). \quad (26)$$

For the polarization of the scattered electrons one obtains

Card 3/6

Polarization effects...

S/185/60/005/004/001/021
D274/D306

$$\vec{\zeta}_f = \vec{\zeta}_i + \frac{(\gamma-1)\sin\theta}{\mu} ([a_1(A_0+2A_1)+2b_1B_1-2c_1B_1]\vec{k} + [a_1(A_0+2A_1)+2b_1B_1-2c_1B_1]\vec{l}-2c_1B_1\vec{n}), \quad (29)$$

μ , a , b , c , A and B are given by expressions involving α , δ , p , Z , e , γ and E , where

$$\gamma = \frac{E}{m} = \frac{1}{\sqrt{1-v^2}} \quad (32)$$

$$\vec{k} = \frac{\vec{p}_1}{|\vec{p}_1|}; \quad \vec{l} = [\vec{n}\vec{k}] \quad (33)$$

In the case of scattering of unpolarized electrons, formula (29) reduces to

$$\vec{\zeta}_f = Ze^2v (1-v^2)^{\frac{1}{2}} \frac{\sin^2x}{\cos x} \frac{1+\alpha^2\sin^2x}{1-v^2\sin^2x} \delta_2 \vec{n} \quad (34)$$

An analysis of formula (34) shows that the polarization and azi-

Card 4/6

Polarization effects...

S/185/60/005/004/001/021
D274/D306

mutual asymmetry of electrons scattered by a nucleus with finite radius is smaller than in the case of electrons scattered by a Coulomb field. With increasing α these quantities decrease; for $\alpha = \alpha_0$ they become zero, and with α further increasing, they change sign. It is noted however, that at the points where δ_2 vanishes, the higher Born-approximations have to be taken into account; therefore, the results are only fully reliable for $\alpha < \alpha_0$. The smaller polarization and azimuthal asymmetry in the case of scattering by nuclei of finite size, as compared to point nuclei, is a result of absence of singularities of the interaction potential between electrons and nuclei of finite radius. Hence such a decrease should take place independent of the charge-density distribution in the nucleus. This conclusion is of a general character and does not depend on the use of the second Born-approximation. There are 7 references: 2 Soviet-bloc and 5 non-Soviet-bloc. TITLE: Determination of the charge density of light nuclei with a generalized model ¹⁹

PERIODICAL: Ukrayins'kyy fizychnyy zhurnal, v. 8, no. 4, April 1963, 431-439

TEXT: The author assumes that the nucleons of the nucleus move in a deformed axisymmetrical potential and that their interaction is accounted for by this potential, so that the charge density of the nucleus amounts to the sum of densities created by the individual nucleons. The charge density created by a single nucleon is determined by the quadratic modulus of its wave function describing the motion of the nucleon in a deformed axially symmetrical potential. He expands the expression for charge density into a series by Legendre polynomials. The first two coefficients of this expansion determine the mean square radius and quadrupole moment of the nucleus, respectively. The author supplies formulas for finding these values readily for nuclei with $Z \leq 20$.

Ed.: M.K. Polshkov; Exec. Ed.: Ye.O. Furshin; Tech. Ed.: A.S. Poloshina.

PURPOSE: This booklet is intended for exploration geophysicists and geologists.
COVERAGE: This collection of articles includes discussions of improvements in
seismic exploration techniques and interpretations of data obtained by the
refracted and reflected waves method of seismic exploration. Individual
articles discuss: the construction of geoelectric maps, improvements in
logging equipment, the standardization of radioactive electro-
operational equipment, and methods for computing labor productivity in geophysical
operations. A diagram to facilitate the interpretation of data and conditions
when using gamma logging of boreholes is described. References accompany
each article.

Methods for Simplifying High-Molecular Substances of Pitch
(Sposoby uproshcheniya vysokomolekulyarnykh veshchestv pika)

PERIODICAL:

Zhurnal prikladnoy khimii, 1959, Vol XXXII, Nr 2,
pp 391-395 (USSR)

ABSTRACT:

The resins obtained in the thermolysis of wood contain from 30 - 70% pitch. The composition of pitch is investigated here in order to find new fields of application for it. The tested samples contained 24.8% neutral substances, 21.4% phenols, and 42.7% acids. After treatment with metallic sodium the phenol-acids were decomposed to substances soluble in ether with a molecular weight of 300 - 500 (34%) and to substances soluble in an alcohol-acetone mixture with a molecular weight of about 800 (60%). The phenol-acids are linked by a carbon-carbon bond.

ASM-SLA METALLURGICAL LITERATURE CLASSIFICATION

Aliphatic chloro-derivatives. I. Chlorination of trimethylethylene. D. V. TISHCHENKO (J. Gen. Chem. Russ., 1936, 6, 1116--1123).—The products of reaction of 1 mol. of Cl_2 with 1 mol. of $\text{CHMe}_2\text{CMe}_2$ (I) at -17° are: CMe_2EtCl (II), $\text{CHMeClCMe}_2\text{CH}_3$ (III), α -chloro- β -methyl- Δ^2 -butene (IV), b.p. $108-110^\circ$, $\text{CHMeClCMe}_2\text{Cl}$ (V), γ -dichloro- β -methylbutene (VI), b.p. 155° , β -trichloro- β -methylbutene (VII), b.p. $73-74^\circ/19$ mm., β -dichloro- γ -chloromethylbutene (VIII), b.p. $79-81^\circ/15$ mm., and β -trichloro- γ -chloromethylbutene (IX), b.p. $102-103^\circ/13$ mm. On further chlorination, (II) yields a mixture of β -trichloro- γ -methylbutene (X), m.p. 170° , and (V), (VII), and (IX). The process is supposed to consist of the reactions: (I) + $\text{Cl}_2 \rightarrow$ (V); (V) \rightarrow (III) + HCl; (I) + HCl \rightarrow (II); (III) + HCl \rightarrow (V) + (VI); (III) + $\text{Cl}_2 \rightarrow$ (VII); (VI) + $\text{Cl}_2 \rightarrow$ (VII) + (VIII); (VII) or (VIII) + $\text{Cl}_2 \rightarrow$ (IX); (V) + $\text{Cl}_2 \rightarrow$ (VII) + (IX) + (X); (III) \rightarrow (IV). (VI) and (VIII) are readily hydrolyzed by aq. KOH to yield alcohols and tarry products, with elimination of HCl. Most of the remaining Cl-derivatives are either unattacked by aq. KOH, or yield unsaturated products; thus, (IX) gives $\text{CHClC}(\text{CH}_2\text{Cl})\text{CHMeCl}$. When treated with quinoline at 150° the compounds

behave differently; thus (V) does not react, (VI) gives isoprene in 10–15% yield, with traces of γ -chloro- β -methyl- Δ^2 -butene (I) (XI), b.p. $108-108^\circ$, (VII) gives β -chloroisoprene (XII) in 30% yield, (VIII) affords tarry products, with elimination of HCl, (X) gives (XII) in 80% yield and (XI), and $\text{CH}_2\text{ClCMe}_2\text{CMeCl}$ gives $\text{CHClCMeCH}_2\text{CH}_3$ (80% yield). α -Chloroisoprenes condense with maleic anhydride to yield HCl and homologues of dihydrophtalic acid.

Chloro-derivatives of aliphatic hydrocarbons.
II. Allylic isomerization of isopentenyl chlorides. D. V. TISCHTSCHENKO. III. Chlorination of $\alpha\beta$ - and $\beta\gamma$ -dichlorobutanes. D. V. TISCHTSCHENKO and A. TICHURBAKOV (J. Gen. Chem. Russ., 1936, 8, 1549—1552, 1553—1558; cf. this vol., 2).
II. $\text{CH}_3\cdot\text{CMe}\cdot\text{CHMeCl}$ or $\text{CHMe}\cdot\text{CMe}\cdot\text{CH}_2\text{Cl}$ yield, when hydrolyzed with H_2O at 70° , a mixture of COMePr^n , $\text{OH}\cdot\text{CHMe}\cdot\text{CMe}\cdot\text{CH}_3$ (α -naphthylurethane, m.p. $91.5-93^\circ$), and $\text{OH}\cdot\text{CH}_2\cdot\text{CMe}\cdot\text{CHMe}$ (α -naphthylurethane, m.p. 103°). The alcohols afford isoprene when passed over MgSO_4 at $230-260^\circ$.
III. $\alpha\beta$ - or $\beta\gamma$ -Dichlorobutane and Cl_2 yield a mixture of $\text{CH}_2\text{Cl}\cdot\text{CHCl}\cdot\text{CHMeCl}$ (I) and $\text{CHMeCl}\cdot\text{CMeCl}_2$ (II). (I), when distilled from KOH, yields a mixture of cis-, b.p. $134-136^\circ$, and trans- $\beta\gamma$ -dichloro- Δ^2 -butene, b.p. $101-103^\circ$, whilst (II) gives a mixture of cis-, b.p. $125-127^\circ$, and trans- $\beta\gamma$ -dichloro- Δ^2 -butene, b.p. $118-118^\circ$. The position of the Cl in the dichlorobutenes is determined by examining the products of ozonolysis. R. T.

CH

Chlorine derivatives of aliphatic hydrocarbons. VI. Reactivity of polychlorides of the allyl type. D. V. Tishchenko. *J. Gen. Chem. (U. S. S. R.)* 7, 658-62 (1937). *C. A.* 31, 4235. To show that in the allyl rearrangement the reactivity of the system depends chiefly on the polar properties of the potentially mobile group and the relative position of the substituents in the mol., $\text{MeCCl:CHCH}_2\text{Cl}$ (I), $\text{MeCH:CClCH}_2\text{Cl}$ (II) and

$\text{CH}_2\text{CClCHClCH}_2\text{Cl}$ (III) (the asterisks indicate the potentially mobile Cl atoms) are sapon. with 2 parts of H_2O and the theoretical amt. of CaCO_3 (cf. *C. A.* 31, 2165). The relative rate of sapon. is 28.5 for I, 0.7 for II and 0 for III. I, b_p 66-7°, d_4^{20} 1.1952, n_D^{20} 1.4604 (Carothers, *C. A.* 26, 5003) gave chiefly 3-chloro-2-buten-1-ol, b_p 67-7.5°, d_4^{20} 1.1172, n_D^{20} 1.4654, M.R.c 26.38 (calcd. 26.43), and 2% methylvinyl ketone. The incompletely sepd. stereoisomeric II (*C. A.* 31, 2165) yielded about equal parts of 2-chloro-2-buten-1-ol, b_p 62-3°, d_4^{20} 1.0935, n_D^{20} 1.4500, M.R.c 26.43 (calcd. 26.43 for $\text{C}_4\text{H}_7\text{ClO}$), and 3-chloro-3-buten-2-ol, b_p 67-8°, d_4^{20} 1.1138, n_D^{20} 1.4623, M.R.c 26.53. III failed to react with CaCO_3 . It reacts with K_2CO_3 in H_2O giving nearly 100% β,γ -dichlorobutadiene polymer. Thus, the introduction of Cl atom in the α -position to the potentially mobile Cl atom inhibits considerably the reactivity of the

latter (sapon.), but does not exclude the possibility of allyl rearrangement. Two Cl atoms in α,α' -position completely inactivate the allyl Cl atom, making the transposition impossible. A Cl atom in the β -position reduces considerably the mobility of allyl Cl atom and completely excludes the rearrangement. VII. Chlorination of 2-chlorobutane. D. V. Tishchenko and A. Churbakov. *Ibid.* 6(3) 6. 2-Chlorobutane, b_p 67-8.5°, d_4^{20} 0.8724 (from 2-butanol and HCl , d. 1.12) treated with less than 2 Cl mols. in the liquid phase gave all the 4 isomeric dichlorides. 2,2- $\text{C}_4\text{H}_8\text{Cl}_2$, b_p 102-4°, d_4^{20} 1.0005, n_D^{20} 1.4300, and 2,3- $\text{C}_4\text{H}_8\text{Cl}_2$, b_p 110°, d_4^{20} 1.0067, n_D^{20} 1.4413, treated with alc. KOH cleave 1 mol. HCl and give the same mixt. of stereoisomeric 2-chloro-2-butene, according to the Zaitsev-Wagner rule. 1,3- $\text{C}_4\text{H}_8\text{Cl}_2$, b_p 132°, is easily sapon. with aq. K_2CO_3 to 1,3-butanediol, b_p 110-11°, d_4^{20} 1.024, n_D^{20} 1.4405, while 1,2- $\text{C}_4\text{H}_8\text{Cl}_2$, b_p 124°, d_4^{20} 1.1182, reacts with aq. K_2CO_3 only at elevated pressure, forming 1,2-butanediol, b_p 101°, d_4^{20} 1.001, n_D^{20} 1.435. The formation of 2,2- $\text{C}_4\text{H}_8\text{Cl}_2$ from 2- $\text{C}_4\text{H}_9\text{Cl}$ with Cl, refutes in this case the rule of Meyer (*J. prakt. Chem. [N. F.]* 46, 161(1892)), supported by Herzfelder (*Ber.* 26, 2032(1893)), that the substitution of second Cl

atom at the C atom contr. a Cl atom is impossible. The work is being continued. Chav. Blanc

ASD-SLA DETAILORICAL LITERATURE CLASSIFICATION

PRELIMINARY REPORT NO. 12
Chlorine derivatives of the aliphatic series XIII
The action of chlorine on *is*-methylstyrene. II
 A. Gutner and D. V. Fishalanka. *J. Gen. Chem. (U. S. S. R.)* 8, 1062-7 (in French, 1937) (1938); cf. *C. A.* 32, 482². In the chlorination of 2-methyl-1-butene (I) with 1 equiv. of Cl₂ at -5° in the absence of a neutralizing agent the liberated HCl reacts with I, giving nearly 90% *tert*-AmCl. The reaction mixt. contains 3-5% of unsatd. monochlorides, chiefly 2-(chloromethyl)-1-butene (II) and some 2,3-dichloro-2-methylbutane. The latter is a deriv. of trimethylstyrene evidently formed in the reaction by isomerization of I. In the presence of NaHCO₃ the reaction proceeds normally, affording up to 44% of

unsatd. monochlorides, contg. chiefly II and some 1-chloro-2-methyl-2-butene and 2-methyl-3-chloro-1-butene. From the dichloride mixt. only 1,2-dichloro-2-methylbutane was isolated. Chas. Blane

Chlorine derivatives of the aliphatic series. XIV. The additive capacity of a double bond at the quaternary carbon. D. V. Fishchenko. *J. Gen. Chem.* (U. S. S. R.) 8, 1232-45 (in French, 1210) (1958); cf. *C. A.* 52, 4827. — The ethylene hydrocarbons and monochlorides with a quaternary C atom at the double bond were treated, with stirring, with approx. 1 mol. of Cl at 0° in the presence of 1.5 mols. NaHCO₃. Me₃C·CMe₂ gave a mixt. of 90% Me(CH₃)C(CH₃)Cl, b_m 111-12°, d₄²⁰ 0.8805, n_D²⁰ 1.4315, and MeCH₂CHCl·CMe₂ gave 60% Et(Me·CH₂)C(CH₃)Cl, b_m 70-72°, d₄²⁰ 0.895, n_D²⁰ 1.4551 and 40% (CH₃)₂CCl, b_m 101-3°, d₄²⁰ 1.022, n_D²⁰ 1.4748. Me₃C·CHCl gave 88% Me(CH₃)C(CH₃)Cl, b_m 108-12°, b_m 10-10°, d₄²⁰ 1.1363, n_D²⁰ 1.4524, M. R. 29.00, and 32% Me₂CClCHCl, b_m 115-6°, b_m 40-7°, d₄²⁰ 1.2588. Me₃C·CClMe gave 80% Me(CH₃)C(CH₃)Cl, b_m 55-7°, b. 124-6°, d₄²⁰ 1.085, n_D²⁰ 1.4513, M. R. 34.52 and 10% Me₂CCl·CClMe, m. 182-3°. The dichloride on boiling is isomerized into 2-methyl-2,3-dichloro-1-butene, b. 151-3°, d₄²⁰ 1.1276, n_D²⁰ 1.4757. MeCHClCMe·CH₂ gave 65% 3-chloromethyl-3-chloro-1-butene, b. 39-40°, contg. about 25% 1,3-dichloro-2-methyl-2-butene, and 30% MeCHCl·CMeCHCl, b. 65-55°, d₄²⁰ 1.2482, n_D²⁰ 1.4753, M. R. 39.04. MeCCl·CHMe gave 55% CH₃·CClCHClMe, b. 111-13°, d₄²⁰ 1.1319, n_D²⁰ 1.4503, M. R. 29.03 and 45% MeCCH₂CHClMe, b. 143-5°, d₄²⁰ 1.203, n_D²⁰ 1.4637, M. R. 33.20. CH₃·C(CH₃)C(CH₃)ClMe, contg. about 25% 1,3-dichloro-2-butene, gave about 6% C₂H₅CH₂·(CH₃)C(CH₃)CHClMe, b. 102-4°, d₄²⁰ 1.4133, n_D²⁰ 1.5033. The trichloride is probably 1,3-dichloro-2-chloromethyl-1-

butene (cf. *C. A.* 11, 1087). CH₃·C(CH₃)CHMe gave 100% CH₃CHClCHClCHClMe, b_m 63-35°, d₄²⁰ 1.4276, n_D²⁰ 1.4881. Thus the results show again (cf. *C. A.* 51, 1000) that the polarization of the double bond at the quaternary C atom produces anomalous reaction with Cl with the formation of unsatd. monochlorides of ethylenes as the chief reaction products and a little dichloride formed by the addn. of 2 Cl atoms at the double bond. With the increasing no. of Cl atoms in the alkyls attached to the quaternary C at the double bond the products of Cl addn. (dichlorides) increase and the products of Cl substitution and isomerization (unsatd. monochlorides) decrease (cf. Ingold, *C. A.* 29, 1057; I. and Smith, *C. A.* 26, 691). XV. The action of quinoline on polyhalides of dimethylenecyclohexene. *Prod.* 1326-9. 1,1,2-Trichlorocyclohexane, b_m 90-7°, d₄²⁰ 1.3288, n_D²⁰ 1.5094, M. R. 42.10, was obtained in 40% yield from 1-chloro-1-cyclohexene and 1 mol. Cl at 0°. The trichloride reacts with 1 mol. quinoline at 210-60°, giving 1,2-dichloro-1-cyclohexene (I), b_m 76.7-7°, m. 26-7°. The hydrolysis of the ozonide of I gave adipic acid. The cleavage of 2 mols. HCl from the trichloride with 2 mols. quinoline forms not the expected chloroallene deriv., according to the Markovnikov law, but gives by transposition of the double bond 2,4-dichloro-1,2-cyclohexadiene, b_m 141-2°, d₄²⁰ 1.0807, n_D²⁰ 1.4055, M. R. 31.29. After 15 months the diene compd. was partially polymerized to a nonvolatile product. Chas. Blanc

Chlorine derivatives of the aliphatic series. XV
Chlorination of isobutylene. I. Dyakonov and D.
Tishchenko. *J. Gen. Chem.* (U. S. S. R.) 9, 1258-61
(1939); cf. C. A. 33, 1190-9. Isobutylene with approx.
an equal vol. of Cl gave, after fractional distn., 90 g. Me-
CCl (I), b. 52-1°, 88 g. isobutenyl chloride (II), b. 71-4-
61 g. 1,2-dichloroisobutane, b. 107-10°, 231 g. of a mixt.
contg. approx. 40% (detd. by hydrolysis) 1-chloro-2-
chloromethyl-2-propene (III) and 10% 1,3-dichloro-2-
methyl-1-propene (IV), b. 131-4°, and a mixt. of tri-
chloroisobutanes, not investigated further. I was identi-
fied by hydrolysis to Me₂COH, m. 25°, b. 80-2°. III and
IV were identified by oxidation of the mixt. of III and IV
with O₂ to give ClCH₂COSe (semicarbazone, m. 142-3°),
and (ClCH₂)₂CO. The chlorination of II at 0° in the
presence of NaHCO₃ also gave a mixt. of III and IV, in
addn. to other products. Based on the exptl. data the
chlorination of isobutylene is an anomalous reaction, simi-
lar to that previously observed for other ethylene hydro-
carbons with a tertiary C atom at the double bond.

John Livak

1A

Chlorine derivatives of aliphatic series. XVI. Vicinal effect. D. V. Tishchenko. *J. Gen. Chem.* (U. S. S. R.) 9, 1280-8 (1939); cf. *C. A.* 33, 4190^{1A}.—The sapon. rate of aliphatic primary, secondary and tertiary 1,2-, 1,3- and 1,4-dichlorides is studied by heating the compds. in sealed tubes with aq. alc. 0.1 N NaOH at the required temps. (30-100°) for 1-13 hrs. and titrating the cold reaction products with 0.1 N NaOH or HCl at definite intervals of time. The compds. tested are: $(CH_3CHClMe)_2$, b. 51.5°; $(CH_3CHClMe)_2$, m. 130-60°; $(CH_3CHClMe)_2$, b. 62-2.5°, d_4^{20} 1.0520, n_D^{20} 1.4405, M. R. 39.53; $CH_3(CHClMe)_2$, b. 142-7°, d_4^{20} 1.0634, n_D^{20} 1.4300; $(CHClMe)_2$, b. 110-17°, d_4^{20} 1.204, n_D^{20} 1.452, M. R. 25.3; $(CH_2Cl)_2$. Again the tabulated results show that in each series the sapon. velocity decreases from 1,2- to 1,4-dichlorides and between the series from the primary to tertiary. With changes in the NaOH concn. the sapon. rate of tertiary dichlorides is practically unchanged, while that of primary and secondary dichlorides decreases sharply. For understanding of the varied reactivity and magnitude of dipole moments of polysubstituted org. compds. the conception of "vicinal effect" is suggested. The latter in the presence of neg. substituents (the valency electronic pair of the link C—X is nearer to X) decreases

the dipole moments of the bond C—X and retards the ionization of atoms or the X groups. Pos. substituents (electron pair is closer to C) decrease the moments of the C—X bonds and facilitate the ionization of X groups. The vicinal effect is more pronounced with the greater propinquity of polar substituents and practically disappears at the 1,4-position. Chas. Blane

3,6-Anhydro-D-glucosin $<1.5\alpha < 1.4$ - anhydride of anhydro-D-glucose). D. Tischenchenko and N. Nosova. *Zhur. Obshch. Khim.* (J. Gen. Chem.) **18**, 1193-7 (1948).
The "acid water" waste from a gas-generating plant (gasification of wood) on concn. to d. 1.35, followed by concn. *in vacuo* (0.5-1 mm.) to a vapor temp. 140° , suffers decomposition and yields 30-5% distillate, b.p. 180° . Fractionation of this yields a fraction, b. $140-5^\circ$, which on prolonged standing crystallizes. The resulting product, $\text{C}_6\text{H}_{10}\text{O}_5$, m. $127-8^\circ$, does not have reducing properties and does not display the reactions of CO or RO groups; the purified material has $[\alpha]_D^{25} 65.7^\circ$ (in water). It hydrolyzes by 5% hot H_2SO_4 gives a max. (6.5%) of reducing substances after 1.5 hrs., after which these decrease again; working up a 2-hr. hydrolysis mixt., after neutralization by Na_2CO_3 , gave a solid, m. $119-19.5^\circ$, identified as 3,6-anhydro-D-glucose; phenylhydrazones, m. $151-5.5^\circ$, osazone, m. 180° . The original substance (4 g.) in 100 ml. water, treated at 70° with 65 ml. Me_2SO , and 100 ml. 30% NaOH , heated 1 hr., and exdtd. with CHCl_3 gave the *MeO* deriv., $\text{C}_{12}\text{H}_{18}\text{O}_6\text{Me}$, m. $38-9^\circ$ (3.7 g.), which was distillable *in vacuo*. The behavior of the original material suggests that it is an anhydride of anhydro-D-glucose, with the most probable structure of 3,6-anhydro-D-glucosin $<1.5\alpha < 1.4$. G. M. Kosolapoff

USSR.

Continuous distillation of gas-producer wood tar. D. Tishchenko, N. Silishchenskaya, and N. Borisova. *Zhur. Priklad. Khim.* 21, 515-21(1948).--Tar leaving the scrubbing system contains up to 40% emulsified water very slowly sepd. by standing. Difficulty in sepn. is due to (1) small difference between sp. gr. of tar and emulsified acid water, (2) viscosity of tar phase of emulsion, (3) small diam. of drops of emulsified water. App. is described which yields oil and pitch directly from the wet tar. Exptl. evidence is presented indicating acid hydrolysis of high-mol. compds. of tar during distn. which increases yield of oil.

New types of terpene transformations. II. Action of chlorine upon α - and β -pinenes. D. Tishchenko and B. Matveev. III. Action of chlorine upon dipentene. D. Tishchenko and V. Folladov (*J. gen. Chem. USSR*, 1960, 28, 906-904, 905-906 [U.S. transl., 931-940, 941-948]).—The possible schemes for the action of Cl_2 upon a branched terpene double bond are discussed and the addition mechanism and substituent mechanism are rejected in favour of a primary reaction of the polarised Cl_2 mol. with the negatively polarised end of the double bond and either evolution of HCl , shift of the double bond (forming an allyl chloride structure), and formation of a monochloride ("anomalous reaction") or addition of the "negative" Cl to the positive end of the double bond forming a dichloride ("classical reaction") (cf. A., 1961, 11, 784). Cl_2 reacts with α - and β -pinenes and dipentene affording products in accordance with the suggested mechanism provided the temp. of fractionation is $< 70^\circ$. The amount of the "anomalous" reaction is measured by the liberation of HCl absorbed in NaHCO_3 .

Cl_2 is passed into α -pinene containing suspended NaHCO_3 at -3 to -5° , and the product is fractionated. When the fractionation is carried out at 13 mm., a temp. of 130° is required and the products identified are β -cymene, myrtenyl chloride (2-chloro-methyl-6 : 8-dimethylbicyclo[3 : 1 : 1]hept-2-ene), $\text{C}_{10}\text{H}_{17}\text{Cl}$ (I), b.p. $67-69^\circ/13$ mm., d_4^{20} 0.865, n_D^{20} 1.4976 (identified by oxidation with KMnO_4 in COMe , to pinic acid), and a product, $\text{C}_{10}\text{H}_{17}\text{O}_2\text{Cl}$ (II) (also obtained on ozonolysis), and 2 : 6-dichlorocamphane (2 : 6-dichloro-1-methylbicyclo[2 : 2 : 1]heptane), $\text{C}_{10}\text{H}_{15}\text{Cl}_2$ (III), m.p. $173-174^\circ$. When fractionation is carried out at 7 mm. (temp.

over

~ 80°) or 2 mm. no HCl is evolved and the products are pinocarveol
chloride (3-chloro-6 : 6-dimethyl-2-methylcyclohex-3 : 1 : 1-hep-
tane), $C_{11}H_{19}Cl$ (IV), b.p. 48--47.5°/2 mm., d_4^{20} 1.016, n_D^{20} 1.4464,
I, b.p. 55--57°/2 mm., and III, and it is concluded that I is a product
of isomerization from IV. Ozonolysis of IV affords 11-oxo-11-oxo-
3-chloro-6 : 6-dimethylcyclo[3 : 1 : 1]heptan-2-one, $C_{11}H_{19}OCl$, m.p.
b.p. 66--67°/0.5 mm., d_4^{20} 1.460, n_D^{20} 1.4900 (semicarbazone, m.p.
223--225°). Similar action of Cl_2 on β -pinene gives I (giving II
on ozonolysis) and a dichloride. Similar chlorination of dipentene
and distillation affords mostly a monochloride shown to be 6-chloro-
1-methyl-4-propen-2'-yl-cyclohex-1-ene (carveol chloride), $C_{11}H_{19}Cl$,
b.p. 71--72°/3 mm., 57--58°/0.35 mm., d_4^{20} 0.9998, n_D^{20} 1.49805,
since its mol. refraction agrees better than with that of the alterna-
tively possible 6-chloro-1-methylene-4-propen-3'-ylcyclohexane sug-
gested by the postulated mechanism, and on treatment with KOAc
in AcOH (b.p. 2 hr.) affords carveol acetate, n_D^{20} 1.47785, and this
on saponification affords (\pm)-carveol, b.p. 129°/28 mm. (II phthal-
ate), m.p. 136--136.5°; phenylurethane, m.p. 94--95°.

The mechanism and end-products of autooxidation of rosin acids. D. Tishchenko, N. Komolukov, K. Kiselev, and S. Maleyskaya. *Zhur. Obshchei Khim.* (J. Gen. Chem.) 20, 1225-35 (1950). The course of the autooxidation appears to proceed by entry of O atoms between C and H in α positions to unsatd. bonds, with resulting formation of OH groups. For primary rosin acids and abietic acid there are 4 such positions and the highest oxidation product should be $C_{20}H_{26}O_4$, which was actually found exptly. for abietic acid. The highest natural autooxidation products are $C_{20}H_{26}O_4$ and are colored, apparently because of oxidation of 2 OH groups to carbonyls, yielding a *p-quinone* structure; these autooxidation products retain the original double bonds and have 2 OH groups. The results disagree with conclusions of Pavlyuchenko (C.A. 30, 31069), who suggested oxidation at unsatd. links as the site of reaction. The fir-resin specimen used as starting material yielded such autooxidation products, which were sepl. by fractional soly. in Et_2O and petr. ether; the products ranged from $C_{20}H_{26}O_2$ to $C_{20}H_{26}O_4$ and were yellow to red in color; all retained 2-2.7 double bonds per mole and 1.8-2.7 OH groups. Heating these colored acids with reducing agents (Zn-AcOH, SO_2 , H_2S) led to loss of color and quant. expts. corresponded to the requirements of a quinone structure. Oxidation of the O_4 fraction with $KMnO_4$ gave AcOH, hydroxybutyric acid, some $(C_6H_5)_2$, and higher acids isolated as Ag salts, with compns. between $C_{11}H_{13}O_4Ag_2$ and $C_{11}H_{13}O_5Ag_2$; the latter heated with MeI gave Me esters, b_p 135-60°, corresponding to $C_{11}H_{13}O_5(OMe)_2$. Five-year air exposure of abietic acid yielded an unstated amt. of the $C_{20}H_{26}O_4$ acid product, yellow, contg. 4 OH groups. *n*-Sapinic acid after 6 months exposure similarly gave the highly oxidized fraction (sol. in Et_2O , insol. in ligroin) which corresponded to $C_{20}H_{26}O_4$.

Vicinal effect. III. Oxygen containing organic compounds. D. Tishchenko (G. M. Kosolapoff, transl. (Leningrad)). *Sbornik State Obshch. Khim.* 2, 1031-32 (1933); *Ch. C.A.* 46, 4488c.—Examination of properties of various O-containing org. compounds shows the following. Accumulation of neg. atoms or groups in an O-contg. molecule leads to strengthening of the bonds of these atoms or groups to the molecule (C atoms). This explains the relative ease of pinacol rearrangement of α -glycols, ease of formation of esters of alcs., dehydration of alcs., and β -hydroxy acids, comparative stability of 1,1-diols and 1,1,1-triols, relative ease of hydrolysis of acetals, ketals, hemiacetals and chloroacetals, as well as the reactivity of halogen in acyl halides, and acidity of H derivs. The vicinal effect is roughly proportional to the dipole moment of the atoms or groups relative to C.

New type of transformations of terpenes. XIV. Reaction of chlorine with camphene. D. Lishchenko. *Zhur. Obshch. Khim.* 23, 1002-13 (1953); *C.A.* 44, 0381d; 48, 3033c, 4481g. Chlorination of camphene (for technique see previous papers) in the presence of enough CCl_4 to dissolve the substance (350 g. camphene, 150 g. CCl_4 , 200 g. NaHCO_3 , 100 g. KMnO_4 , 750 ml. HCl) gave 50% products of "anomalous" reaction. There are formed 3 primary products: chlorocamphene (I), 7-chlorotricyclene (II), and 3-chloromethyl-2,2-dimethylbicyclo[2.2.1]hept-3-ene (III); the latter forms, contrary to the Bredt rule (cf. T., C.A. 44, 7810d). Some 40% camphene dichloride is formed in the "normal" reaction. Ozonolysis of I gave 30% camphenil-

one, 15% HCl , and the trichloride $\text{C}_{10}\text{H}_{15}\text{Cl}_3$, m. 127-8°, which is satd. III is readily sapond., through the acetate, to the corresponding terpenol, m. 59.5-60.0°, the acetate, $\text{C}_{10}\text{H}_{17}(\text{CO}_2)_2\text{O}$ in C_6H_6 gave the II phthalate, m. 142-3°; if H_2O is present in this reaction, the camphenol isomerizes to the corresponding aldehyde, b.p. 88-9°, d. 0.8525, n_D^{20} 1.4076, yielding camphenilaldehyde semicarbazone, m. 207-8°, and another unknown semicarbazone, m. 148-9°, which is more sol. Camphenol in the presence of strong acid vapors is transformed into camphor (inactive form, m. 176-8°). The initial mixt. of I, II, and III is sepd. after treatment with AcONa which permits isolation of unreactive I, b.p. 53-4°, d. 1.018, n_D^{20} 1.40245, a mixt. of cis and trans forms which reacts slowly with iso-AmONa in refluxing iso-AmOH, yielding the iso-Am ether of camphenilaldehyde

enol, b.p. 123-5°, d. 0.917, n_D^{20} 1.4550; a reaction run in sealed tube at 210° gave the ether, b.p. 128-21°, d. 0.916, n_D^{20} 1.4729. The ether heated with HCl gave camphenilaldehyde and iso-AmOH. The enol, I, II, and III mixt. with BzO_2H in CHCl_3 gave a camphene chloride oxide, $\text{C}_{10}\text{H}_{15}\text{OCl}$, m. 90-110°, along with other products. I with KMnO_4 in aq. AcOH gave camphenolone, m. 105-6°, and dehydropentane gave a hydrocarbon, m. 36-42°, b.p. 151-1°, identified as tricyclene. Camphenol II phthalate with aq. KMnO_4 gave a neutral product without CHO groups, apparently a

diketone etc., $\text{C}_{10}\text{H}_{16}\text{O}_4$, m. 109-70°. Camphenol with 4% KMnO_4 gave ketopinonic acid, $\text{C}_{10}\text{H}_{16}\text{O}_4$, m. 230-2°. Stronger oxidation with concd. aq. KMnO_4 gave cis-apocamphoric acid, m. 208-9° (anhydride, m. 175-6°), transcamphoric acid, $\text{C}_{10}\text{H}_{16}\text{O}_4$, m. 166-7°, and AcOH . The ozonolysis products of I appear to contain a lactone, which could not be isolated in a pure state, but was detected by titration with hot NaOH .

Title: Recovery of Guaiacol from Wood-Chemical Phenols

Original

Periodical: Gidroliznaya i lesokhim. prom-st, 1956, No 3, 6-8

Abstract: Two methods have been worked out for recovery of guaiacol from wood-chemical phenols: (1) by formation of acid guaiacolate of ammonia on interaction of NH_3 with the phenols (180-212° fraction); at low temperature the guaiacolate crystallizes out is separated by filtration from the admixtures and is decomposed at 100° to yield guaiacol and ammonia; (2) by precipitation of Mg guaiacolate from alkaline solution of phenolates in the process of separation of wood-resin oils (180-212° fraction) into phenols, acids and neutral substances. Mg and NaOH are regenerated. Pure crystalline guaiacol has been isolated with a yield of up to 75% of the amount contained in the oil.

TITLE: Additiveness of a Double Bond in Quaternary Carbon. Reaction of Chlorine with 1,3-Dienes (Additivnaya sposobnost' dvoynoy svyazi pri chetvertichnom uglerode. Deystviye khloro na 1,3-dieny).

PERIODICAL: Zhurnal Obshchey Khimii, 1957, Vol. 27, No. 1, pp. 227-233 (U.S.S.R.)

ABSTRACT: In order to test the applicability of the M. D. L'VOV reaction to other 1,3-dienes with quaternary carbon atoms, the authors investigated the reaction of Cl with four conjugated dienes with central and end disturbances of the conjugation. The L'vov reaction was found to be the basic addition reaction in 1,4 and 1,2 positions and subordinate in 3,4 position. A new exception to the Thiele law was established for 1,3-dienes according to which double bonds can react separately during central and end disturbances caused by alkyls. The study of the structure of chlorodienes which appear to be allyl type chlorides (their chlorine atom was slightly saponified) was connected with certain known difficulties due to the allyl regroupings. In two cases ozonolyses showed the monochloride to be a mixture of allyl isomers. If the reaction between

Card 1/2

Additiveness of a Double Bond in Quaternary Carbon ⁴⁸²

the chlorine and one of the equivalent bonds is abnormal, the negative induction effect of the chlorine atom will polarize the remaining double bond in the diene monochloride and depolarize the newly forming bond.

The remaining double bond being subjected to the coordinated effect of two methyl groups and a Cl-atom becomes more reactive than the double bonds of the basic hydrocarbon which leads to the formation of diene dichloride. It was observed in three separate cases that the Cl-atom depolarizes monochloride double bonds and they remain intact.

TITLE: New Type of Terpene Conversions. Part 17. Reaction of Chlorine with omega Chlorocamphene (Novyy tip prevrashcheniy terpenov, XVII. Deystviye khloro na omega-khlorkamfen)

PERIODICAL: Zhurnal Obshchey Khimii, 1957, vol 27, No 2, pp. 377-379 (U.S.S.R.)

ABSTRACT: Reference is made to the anomalous M.D.L'vov reaction which during the reaction of chlorine with camphene showed the lowest specific weight in comparison with other terpenes. It was proven during the chlorination of omega-chlorocamphene that the specific weight of the "anomalous" reaction should be higher than in the case of camphene because the negative inductive reaction of the Cl atom strengthens the polarization of the double bond necessary for anomalous reaction. The presence of unsaturated camphene dichlorides and dichlorides of bicyclo-(1,2,2)-3-dichloromethyl-2,2-dimethylheptene-3 in the mixture was proven in spite of the Bredt statement to the contrary. The percentage of the

Card 1/2

 TITLE: About the Structure of Pyronenes (O stroyeni pironenov)
 PERIODICAL: Zhurnal Obshchey Khimii, 1957, vol 27, No 2, pp. 379-384 (U.S.S.R.)
 ABSTRACT:

Investigations were conducted to establish the authenticity of the structural formulas of pyronenes as introduced by Dupont-Dulou (2). None of the formulas were found to have sufficient bases. Ozonolysis and oxidation of beta-pyronene with potassium permanganate showed that it is not identical with the beta-pyronene described by Dupont but rather a mixture of more than 80% 1,1,3-trimethyl-2-methylenecyclohexene-3 and less than 20% of 1,1,2,3-tetramethylcyclohexadiene-2,4. The correctness of structural formulas for gammapyronene, alpha and delta-pyronenes was also found as highly doubtful. It is shown how unreliable structural formulas can be when they are written on the basis of conversions not excluding the isomerization phenomena, certain qualitative reactions, etc.

TITLE: Acid Condensation of Lignin (Kislotnaya kondensatsiya lignina)

PERIODICAL: Zhurnal prikladnoy khimii, 1959, Nr 1, pp 157-166 (USSR)

ABSTRACT: The author tries to establish some relation between the modern concepts on the lignin structure and the phenomenon of its "condensation" or "disactivation". He draws an analogy between the chemistry and technology of phenol-aldehyde resins and the chemistry of the processes of lignin condensation. He points out that phenols react with aldehydes in the presence of alkalis and acids leading finally to the formation of polycondensates, although the condensation does not take place if one of the components of the reaction contains a sulfogroup [Ref. 3]. Therefore the author holds that the phenomenon of condensation of the wood pulp lignin under various reactions and also the protective (against acid condensation) effect of a preliminary introduction of sulfogroups are sufficiently well explained by the analogies from the chemistry of phenol-aldehyde condensates. He disagrees with the competitive viewpoints of Erdtmann [Ref. 24] and Lindgren [Ref. 32] and adheres to the opinion of Harris and Bergstrom [Ref. 33] though pointing out the insufficient generality of the latter.
